

Photometry of Uranus and Neptune, 1972–2016

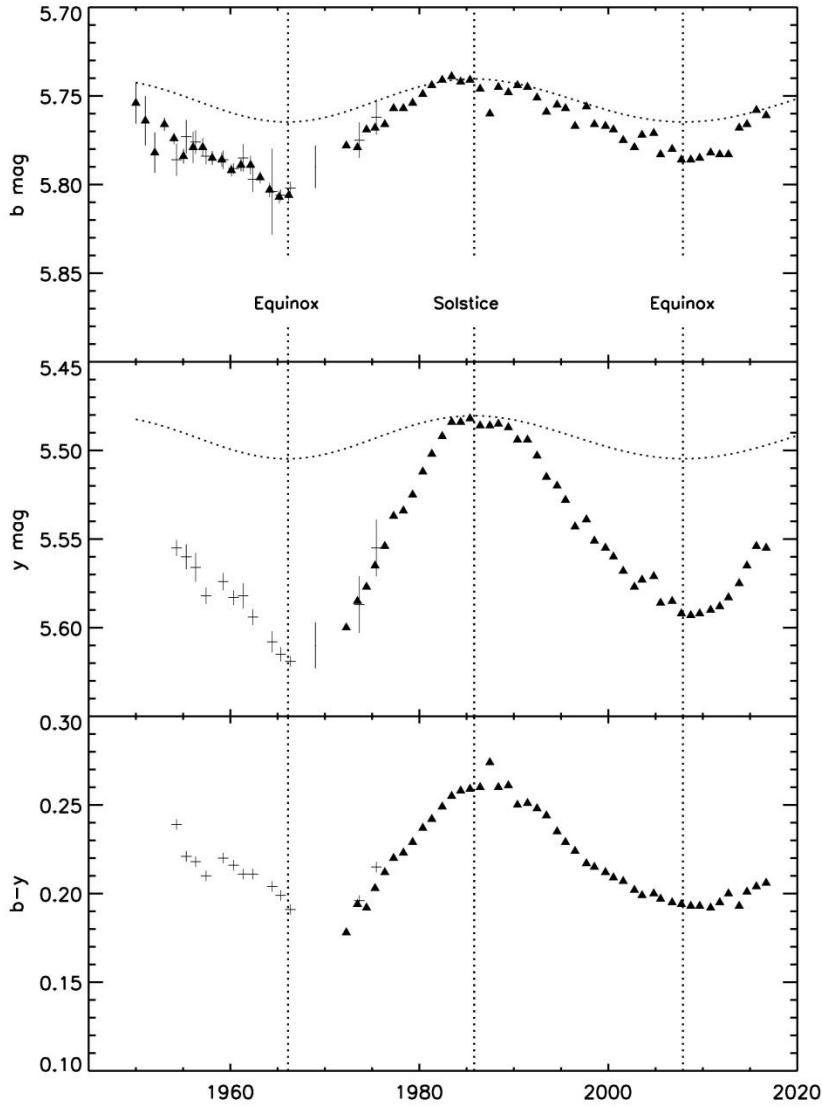

At Lowell Observatory, we have made b (472 nm) and y (551 nm) photometric measurements of Uranus and Neptune at every opposition from 1972 to 2016 (Lockwood 1977, 1978; Lockwood and Thompson 1999, 2002; Lockwood and Jerzykiewicz 2006; Hammel and Lockwood 2007). Each year we observe these planets on at least a few (and sometimes a dozen or more) nights, comparing their brightness with that of two nearby comparison stars of roughly solar color. We adjust the differential magnitudes to a solar phase angle of zero and to standard epoch 1950 heliocentric opposition distances of 19.191 and 30.071 AU, respectively.

Separate observations of a running 5-year string of comparison star pairs including those for a particular apparition tie the system of comparison star magnitudes into our local standard b , y photometric system.

The figures show the light curves in b , y , and b - y color and the tables list the mean opposition magnitudes updated through the 2016 apparition.

Lightcurve of Uranus. (top) b magnitude. Triangles – differential B magnitudes transformed to b , 1950–1966, and b magnitudes 1972–2016; crosses – B magnitudes from two-color photometry, 1954–1966, 1973, 1975, converted to b (offset by +0.15 year for clarity). (center) y magnitude. Triangles – differential y magnitudes; crosses – V magnitudes 1954–1966, 1973, and 1975 converted to y (offset by +0.15 year for clarity). (bottom) $b-y$ color. Triangles – $b-y$ color; crosses – $B-V$ converted to $b-y$. The dotted line indicates the “geometrical lightcurve” variation due to oblateness and apparent area on the sky as Uranus circles the Sun. All error bars are 2
